Wakeful Dreams

some ideas and hopes for fundamental physics

"LHC Physics"

Unification of Charges

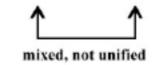

The quantum numbers of quarks and leptons make a compelling case of something like SO(10) unification, now more than ever:

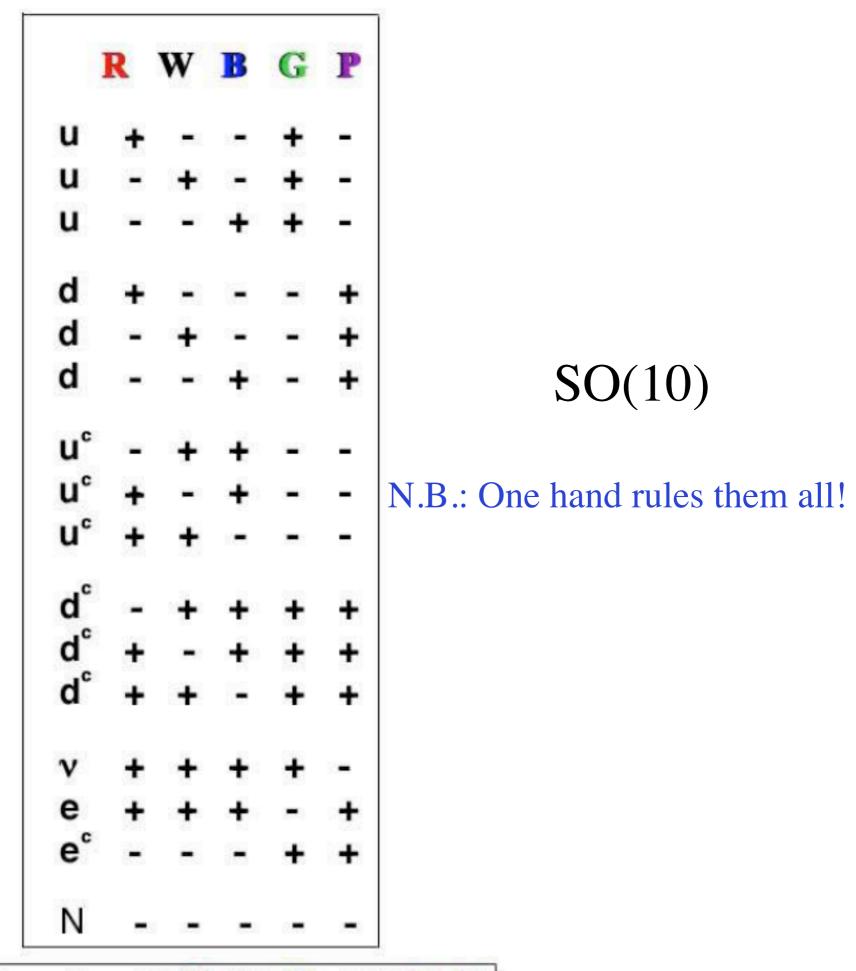

Right-handed neutrinos have been "found". (More precisely, there is evidence for neutrino masses entirely consistent with expectations.)

No exotics have been found.

$$\begin{pmatrix} u & u & u \\ d & d & d \end{pmatrix}_{1/6}^{L}$$
$$\begin{pmatrix} v \\ e \end{pmatrix}_{-1/2}^{L}$$
$$\begin{pmatrix} u & u & u \end{pmatrix}_{2/3}^{R}$$
$$\begin{pmatrix} d & d & d \end{pmatrix}_{-1/3}^{R}$$
$$\begin{pmatrix} e \end{pmatrix}_{-1}^{R}$$
$$v^{R}$$

SU(3) x SU(2) x U(1)

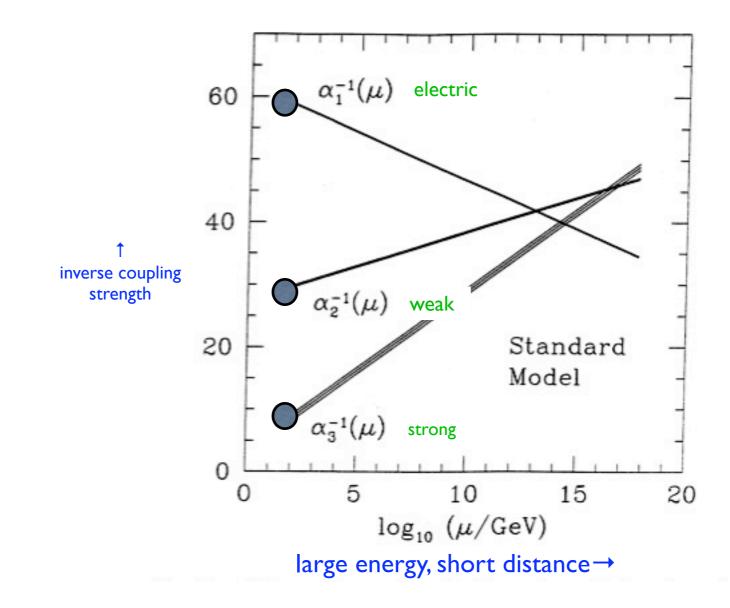

Hypercharge Y = -1/6 (**R**+**W**+**B**) + 1/4 (**G**+**P**)

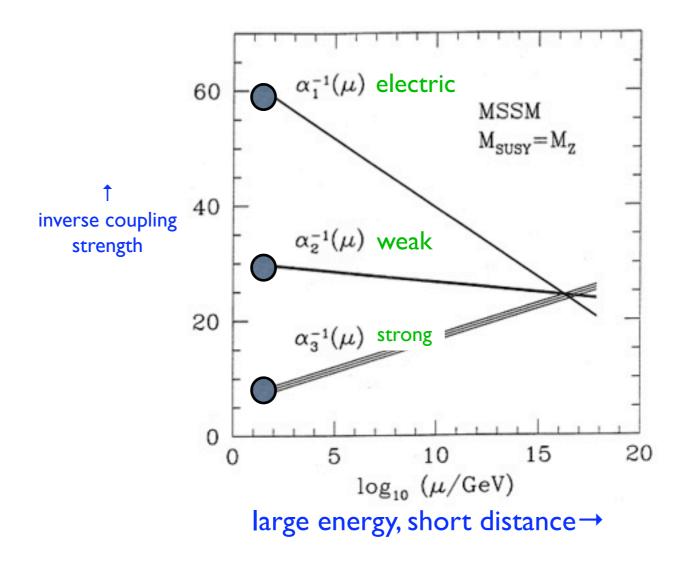

Unification of Couplings

The unification of couplings does not work well if we extrapolate the minimal standard model.

It works much better if we include lowenergy supersymmetry (SUSY).

Unification **V** SUSY

.

The unification calculation is only mildly sensitive to SUSY masses, but marginally favors heavy (multi-TeV) sfermions.

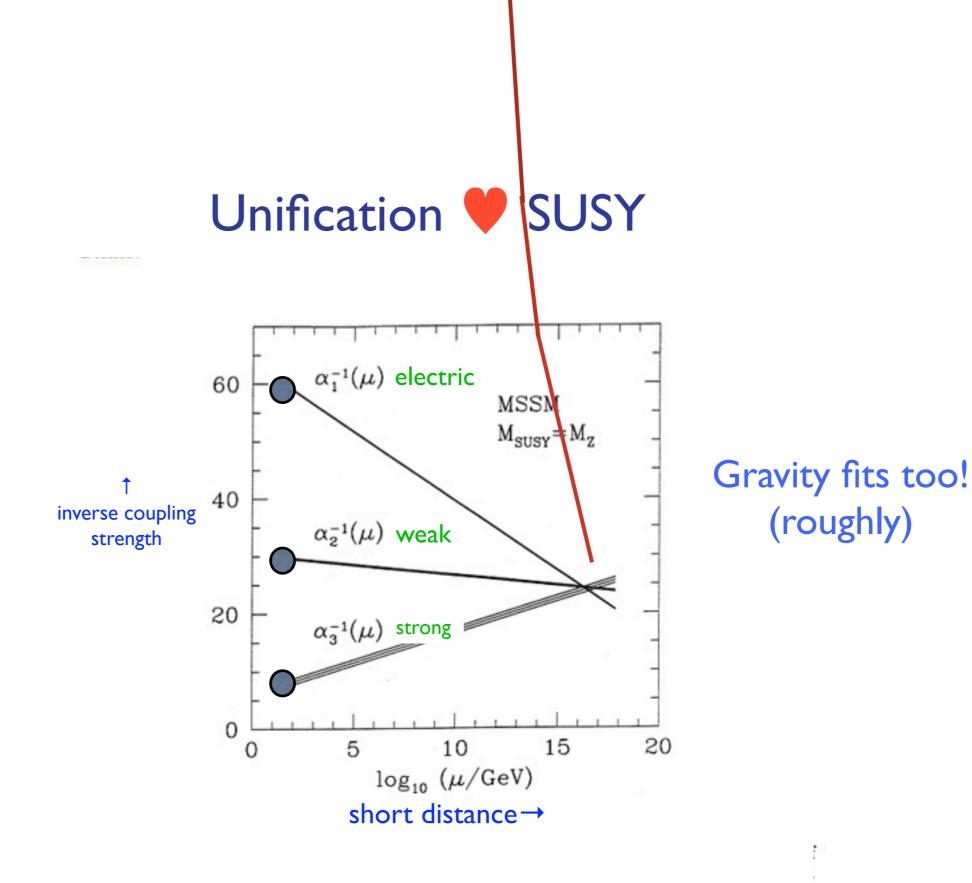

More generally, the unification is only mildly sensitive to addition of complete SU(5) multiplets.

The emergence of a new, very high scale is profoundly significant:

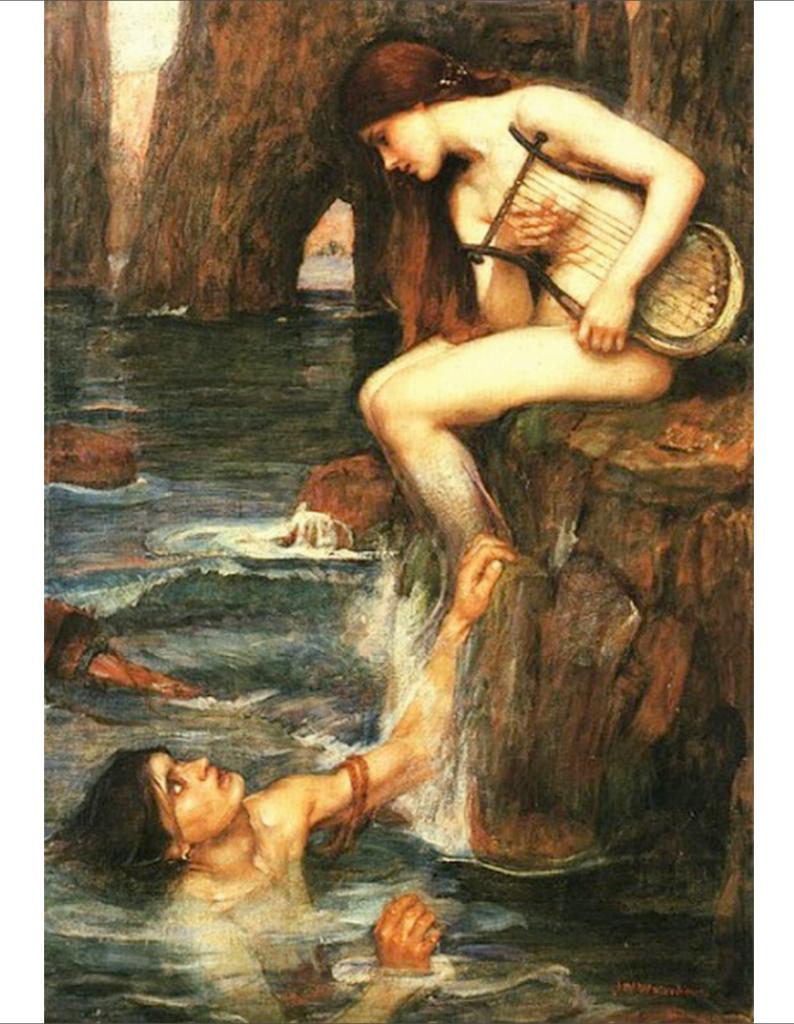

It makes unification including gravity plausible.

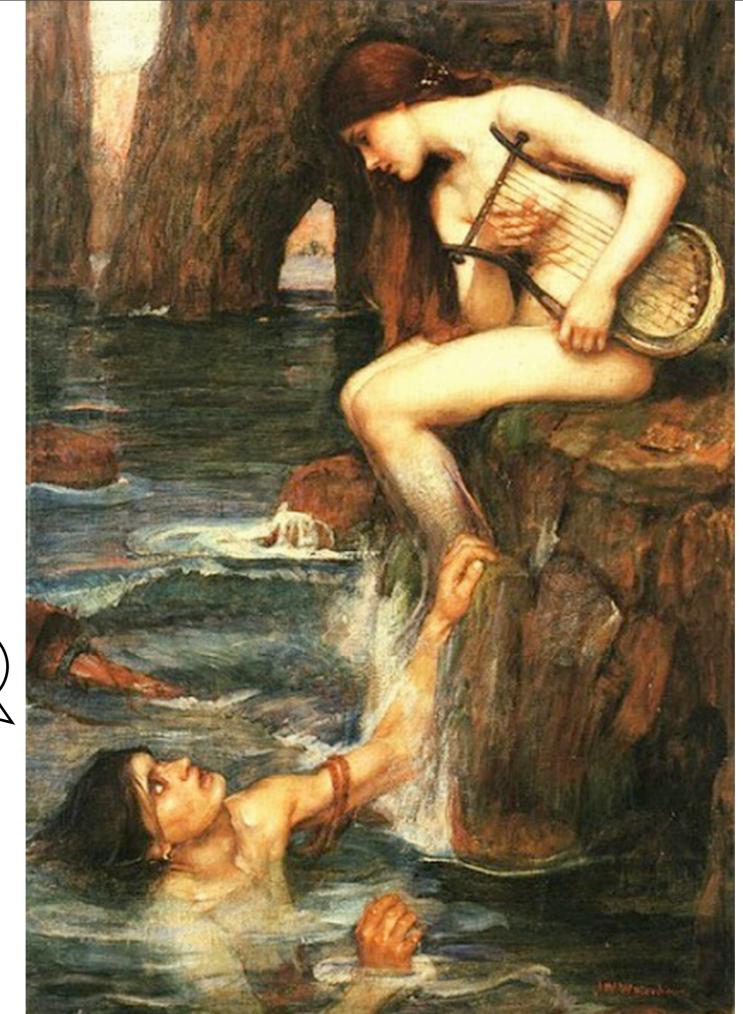

It suppresses proton decay*.

*But the safety margin is thin!

What Kind of Girl is this SUSY?

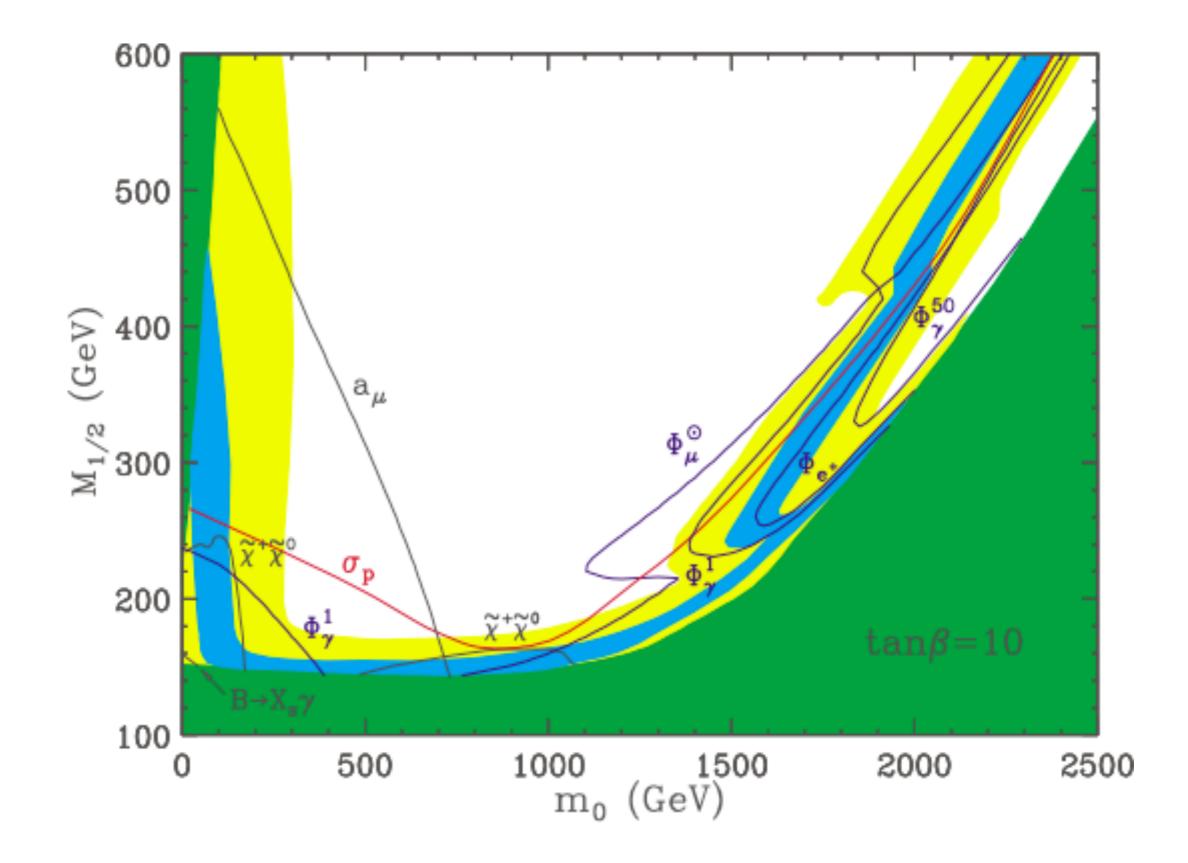

Susy?

Shy, for one thing: many suggested consequences (CP violation, flavor violation, proton decay, radiative corrections ...) have not been seen.

(Note that this is an equally or more severe problem for ideas that propose more powerful and less cancellationprone interactions, e.g. - technicolor, notso-small extra dimensions.) Those unobserved effects are uniformly suppressed for heavy sfermions; so this too suggests that the sfermions are heavy.

A possible difficulty with heavy sfermions is too much dark matter, i.e. overproduction of the *nominal* lightest supersymmetric particle (NLSP).

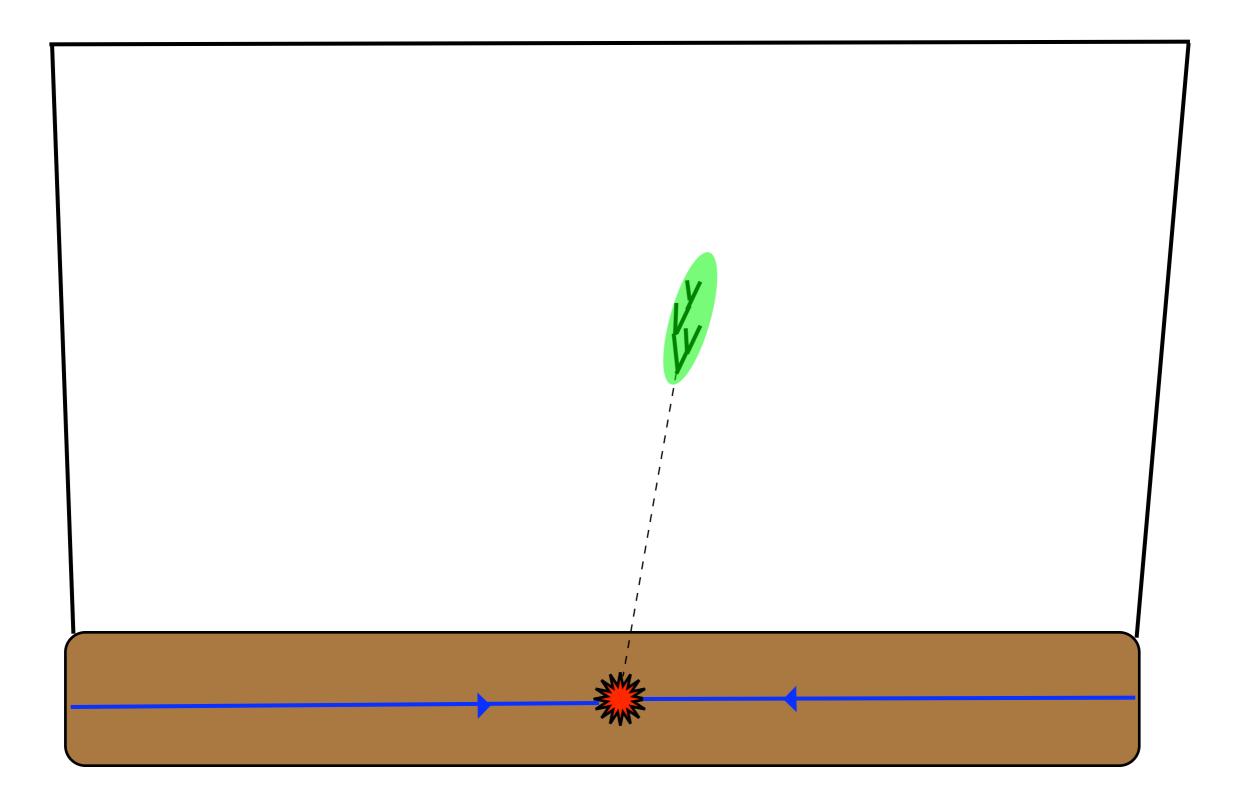

A logical, and I think beautiful, possible explanation is that the nominal LSP decay into a much lighter, very feebly interacting particle, specifically:

$$\tilde{\chi} \rightarrow \tilde{a} + \gamma$$

This, and several other, ideas suggest the possibility of long-lived ($\tau \ge 10^{-5}$ s.) heavy, very weakly interacting particles.

Detecting these will be a challenge.

One possibility might be to adapt cosmic ray ("Fly's Eye") technique:

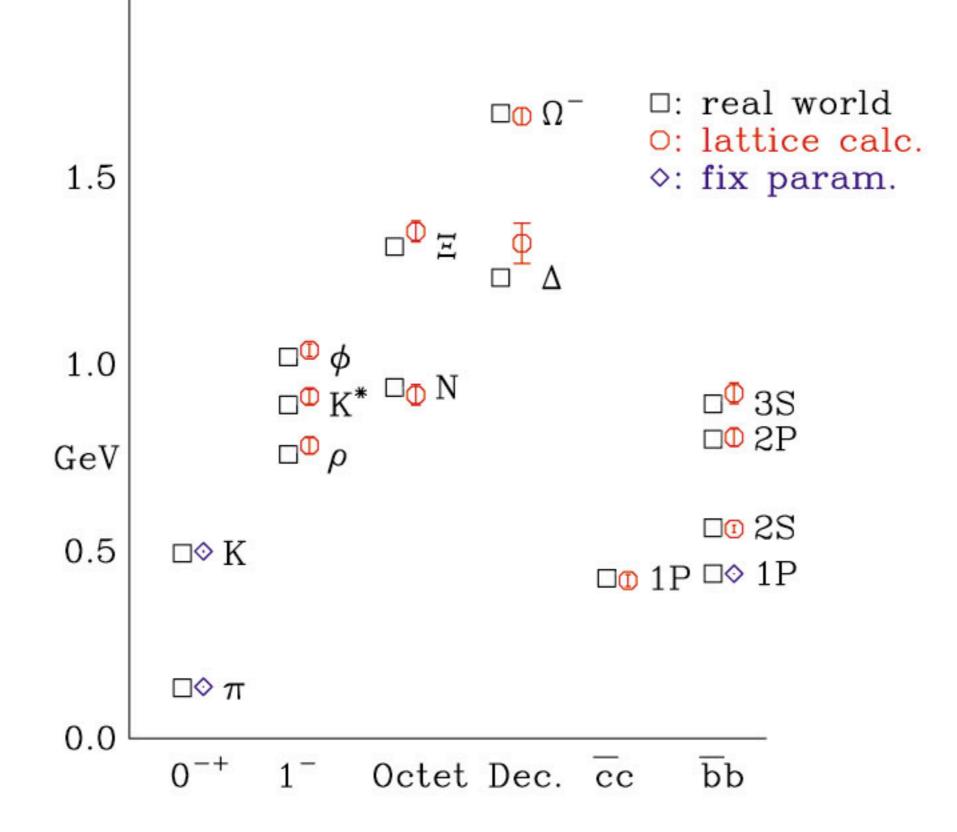

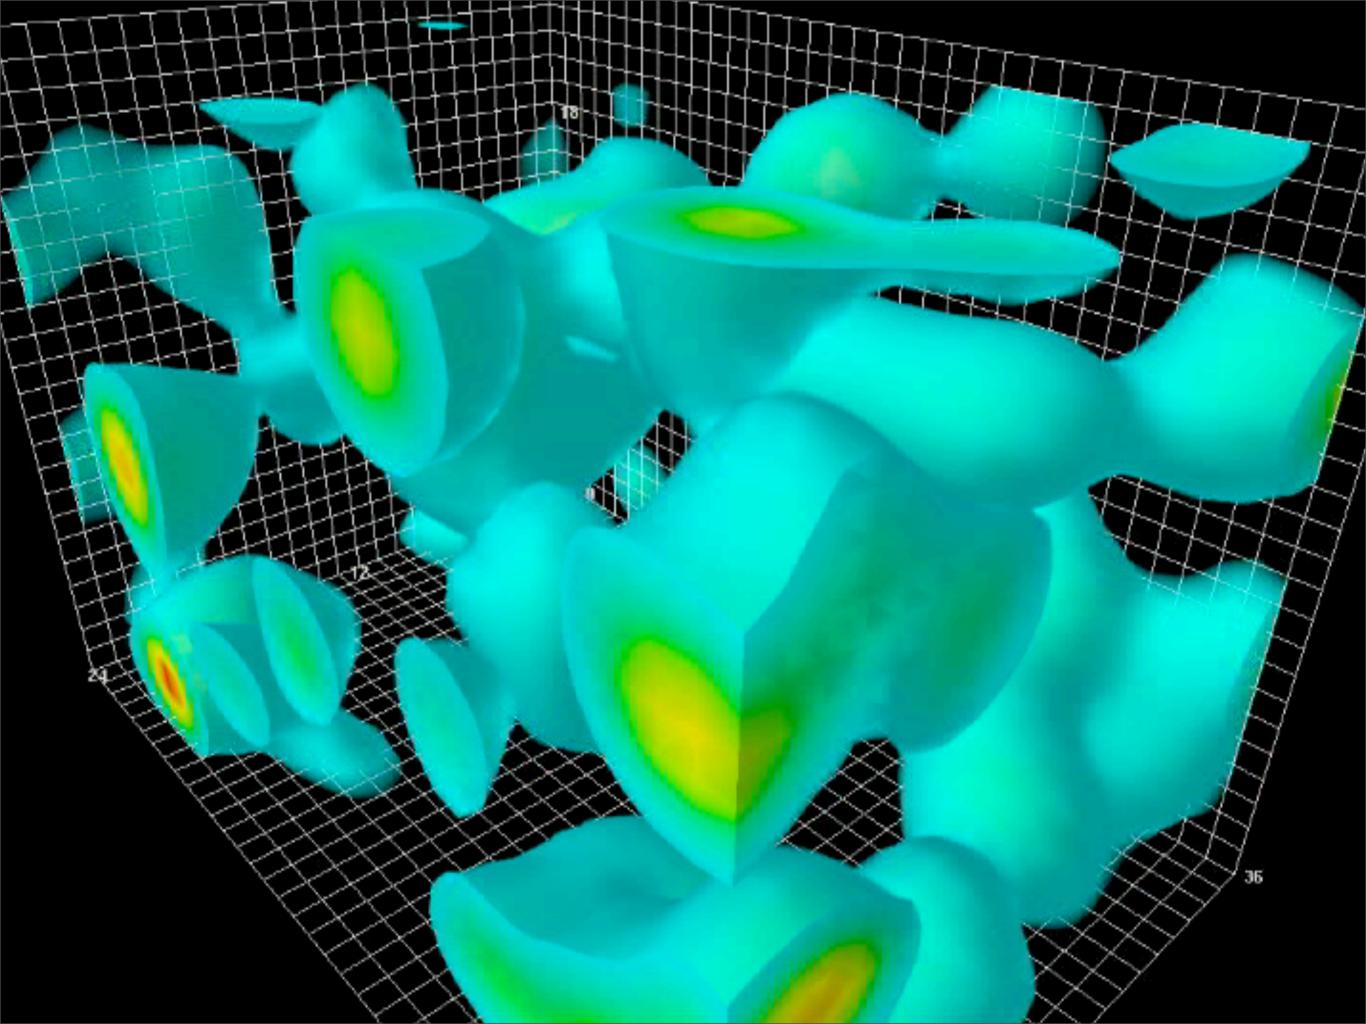

Of course there's infinitely more one might say about LHC physics ...

... but what we really want is for the machine to start talking!

" QCD Physics"

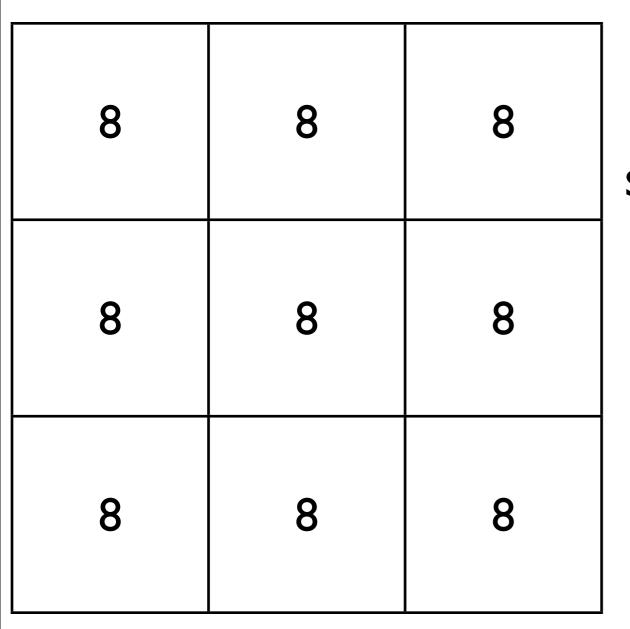

triumphs, challenges

Many qualitative challenges remain, e.g. glueball clarification, "Regge" spectroscopy, nuclear and ultranuclear physics ... as well as bread-and-butter, useful matrix element calculations. Finite baryon density is very hard to handle, due to the notorious sign (actually, phase) problem. This is problem plagues condensed matter physics, and for that matter chemistry, as well.

There is an idealized version that does seem approachable, with interesting connections to the Mott problem.

What Happens?

low density: separate glueballs (?)

high density: screening plasma (?)

"metal"

""

intermediate density: pairing (??)

And in Conclusion ...

What Does It All Mean?

Facts?

Process?

New powers?

Inspiration
