Introduction

$$\lambda = \frac{\lambda_u}{2n\gamma^2} \left(1 + \frac{1}{2}K^2 \right) \quad K = \frac{B_0 e \lambda_u}{mc 2\pi}$$

TOMCAT

The X-ray tomographic microscopy beamline at the Swiss Light Source

Non-destructive, high-throughput, high-resolution, 3D imaging technique:

1. Wide spatial resolution: nano-micro-meso scales (0.1-10 μm)
2. High density resolution enhanced by phase contrast
3. Broad range of sample sizes (10 μm - 20 mm)
4. High temporal resolution: 3D data acquisition in less than 1 s
5. In-situ, operando, in-vivo investigations

Spatial Resolution
10 microns - 0.1 microns

Density Resolution
Phase contrast imaging

Ultra-fast tomography
Living fly

In-situ capabilities
Furnace/Cryo/Traction
Electrochemistry

TOMCAT I-TOMCAT @ SLS2.0

- Higher spatial and temporal resolution
- Larger samples, denser material
- More chemical information

The new μ -Tomography beamline of SL S2.0

The magnetic field optimization of RE-Ba-Cu-O (REBCO, RE = rare earth) bulk superconducting undulators is a fundamental step toward their implementation in an accelerator driven photon source, like a synchrotron or a free electron laser. In this article, we propose a sorting algorithm to reduce the undulator's phase error based on the reconstruction of the trapped current inside the bulks of a staggered array undulator. The results obtained with a YBCO short prototype field-cooled down to 10 K in a 10 T magnetic field are reported. Finally, its performance is critically discussed in light of 2D magnetic field maps of its individual components, obtained at LN₂ after the magnetization tests.

Single Disk characterisation

We have manufactured additional 200 disks from CAN-GdBCO / EuBCO & NS-GdBCO

All of them will be individually cooled in 1T down to LN2 and 2D field mapped, on both sides, with the aim to spot the broken ones / and to pre-sort them with respect to their strength

It looks a perfect result... BUT:

- “We” paid the raw-bulks about 2600 € each
- NS does not deliver REBCO bulks outside Japan...
- Since 2023 NS decided not to deliver anymore bulks to customers also in Japan... they are keeping this activity as an internal R&D.

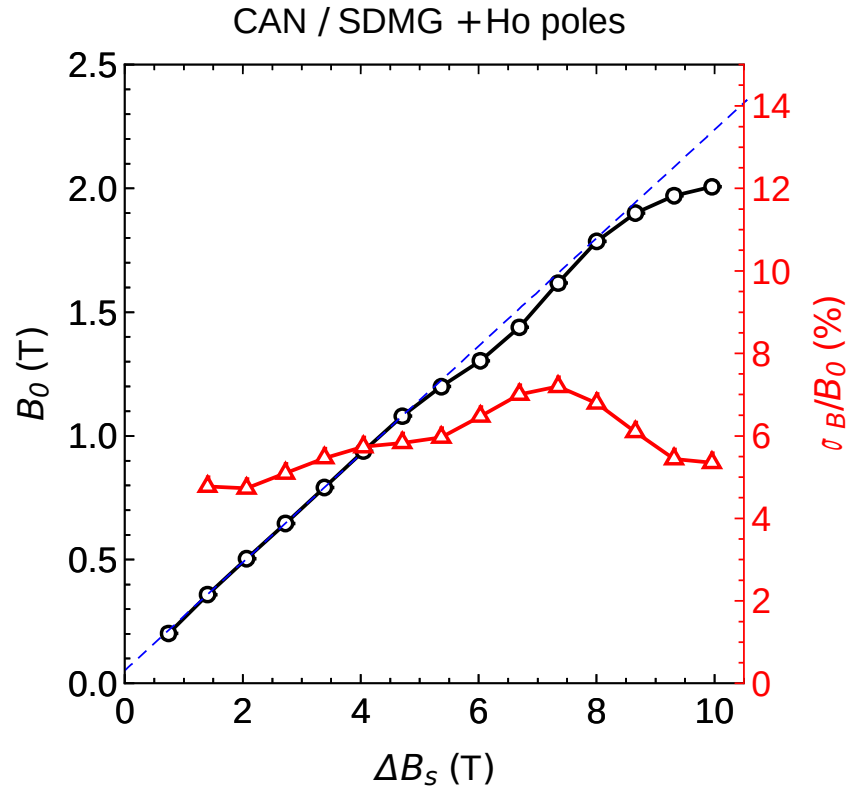

✉ ARE WE BACK TO SQUARE ONE????

- **Single-direction Melt Growth (SDMG)** is a novel approach for REBCO single-domain bulk growth, where a grown bulk from a REBCO system with higher peritectic temperature is used to seed the grown bulk (instead of a NdBCO thin-film seed, which is used for both TSMG and TSIG). The main advantage of this approach is that the bulk is composed exclusively of the c-growth region, unlike TSMG-grown bulks. Therefore, the expected homogeneity is significantly higher in SDMG-grown bulks, as no growth interfaces are present in the bulks.

High Temperature Superconducting Undulator for iTomcat beamline at PSI

FERMILAB-POSTER-21-120-TD

Superconducting Undulators

Superconducting Undulators (SCUs) are the natural continuation in the evolution of insertion devices. The use of permanent magnets has been pushed to the limit by installing the arrays directly in the beam UHV to reduce the gap (in Vacuum Undulators (VU)) and even further by cooling them down to cryogenic temperatures to increase the permeance field (Cryogenic Permanent Magnet Undulators (CPMU)). In order to further increase the magnetic field of these devices, a jump in technology is required, hence the implementation of superconductivity. Development programs both in the US and in Europe have shown that SCUs generate stronger field on axis than comparable permanent magnet-based devices and that the use of superconductivity does not compromise the operation of synchrotron storage rings or FELs. For period lengths above 10 mm, SCUs made out of NbTi show a significant improvement in field on axis compared to CPMUs; furthermore, a large portion of the superconducting technology potential, Nb₃Sn and HTS, has yet to be exploited. Both HTS undulators, as proposed by PSI, allow to extend the functional capability of these devices below 10 mm period length.

Permanent Magnets	Vacuum Undulators (VU)	Cryogenic Permanent Magnet Undulators (CPMU)	NbTi Superconducting Undulators (SCU)	Nb ₃ Sn and HTS Superconducting Undulators (SCU)
Traditional design	Ultra vacuum tube	Improved B field	Highest B field	Permeance limited
Limited size	Reduced distance of magnet	Increased permeance	10 K design	Lower field
Complex design	Simpler design	Better performance	Electromagnet	High field
Low performance	Good performance	Better performance	Best performance	Best performance

Superconducting coil conductor	Nb ₃ Sn & NbTi
Maximum magnetic field	12T
Operational magnetic field	10T
Maximal ramp rate	3mT/s
Maximal ramp rate ($\leq 15T$)	1mT/s
Ramp rate ($\leq 15T$)	50mm
Warm bore diameter	5m
Length of the good field (1% $\times 15mm$)	<math>< 0.1mT</math>
Stray field along the beam axis > 1.5m from the center	<math>< 1mT</math>
Radial stray field from the center outside the cryostat	HTS
Current leads conductor	HTS
Maximum current	1.0 kA
Cooling system	Cryocooler
Operating temperature	$\sim 4K$
Permanent made	NO

High Temperature Superconducting Undulator for ITomcat beamline at PSI

FERMILAB-ATM-2018-01-138-03

Superconducting Undulators

Superconducting undulators (SUs) are a type of undulator that uses superconducting magnets to generate a high magnetic field. This allows them to produce high-energy synchrotron radiation. SUs are used in a variety of applications, including X-ray free electron lasers (XFELs) and synchrotron light sources. They offer several advantages over conventional undulators, including higher magnetic fields, longer undulator lengths, and lower power consumption.

The undulator is designed to operate at a magnetic field of 1.5 T. It is powered by a superconducting magnet system that is cooled to 4.2 K. The undulator is used to produce synchrotron radiation for the ITomcat beamline at PSI.

The undulator is designed to operate at a magnetic field of 1.5 T. It is powered by a superconducting magnet system that is cooled to 4.2 K. The undulator is used to produce synchrotron radiation for the ITomcat beamline at PSI.

Vacuum chamber R&D

- a) Winding phase of the solenoid with a glass fiber insulated RRP Nb₃Sn wire;
- b) assembly of the copper sleeve for conduction cooling;
- c) after the installation of the SS outer cylinder, ready for the Heat Treatment (650°C);
- d) after HT, ready for potting with epoxy resin;

Conclusions & Outlooks

- We demonstrated high magnetic field (2T) in a short sample staggered array undulator made of GdBCO bulks HTS with 10mm period length and 4mm gap.
- Tape stacking is not giving the expected lower phase error and the field strength is substantially lower than bulks.
- The GdBCO bulk made by CAN out of the novel SDMG process are now our baseline
- Holmium poles deliver higher fields than FeCo even if they are not single crystals...
- A preliminary optimisation of the charging reduced the time required from 10 to 4h
- The delivery of the "Cryo-Solenoid" to PSI is planned for 2Q 2025, then we will start an intense measurement campaign to demonstrate a phase error as low as few degrees before installing the device in SLS2.0 at the beginning of 2026.
