Polymorphism, structure and dynamics investigations of 4-n-heptyl-2',3'-difluoro-4'-undecyloxybiphenyl and 4-n-heptyl-2',3'-difluoro-4'-nonyloxybiphenyl

Tuesday, July 7, 2015 6:30 PM (1 hour)

4-n-heptyl-2',3'-difluoro-4'-undecyloxybiphenyl (4HFDB) and 4-n-heptyl-2',3'-difluoro-4'-nonyloxybiphenyl (4HFNB) are liquid crystalline compounds of chemical formula $C_{77}H_{154}C_6H_4C_6H_2F_2OC_{11}H_{23}$ and $C_{77}H_{154}C_6H_4C_6H_4C_6H_2F_2OC_9H_{19}$, respectively, i.e. they differ in the length of the alkyl chain. The latter appears to be strongly affecting their physicochemical properties. The crystal phase, when heated, melts to isotropic liquid at 315 K for 4HFDB and 307 K for 4HFNB. Upon cooling, we identify the following sequences (via DSC scans): IL (309.5 K) SmA for 4HFDB, and IL (303.9 K) N (302.5 K) SmA for 4HFNB. More detailed information on the changes in structure and dynamics of 4HFDB and 4HFNB at the phase transitions comes from X-Ray diffraction, polarizing microscopy and Fourier absorption infrared spectroscopy. Both compounds crystallize in orthorhombic structures (space group $Pmmm$) at RT. The a lattice parameter, closely related to the molecule length, was 29.9(1) Å for 4HFDB and 27.4(2) Å for 4HFNB. Both liquid mesogens are glass-formers and the glass transition temperature was observed about 210 K and 230 K for 4HFDB and 4HFNB, respectively. The vibration C-F mode is not an easy task to analyze due to a strong influence of other vibrations. Moreover, substitution of original hydrogens with fluorine causes a significant shift of bands towards higher frequencies. In order to interpret the experimental results of dynamics, calculations were carried out using Mopac and Dmol3 contained in the Materials Studio package.
